ABSTRACT

A major objective of the European Commission (EC) is to strengthen the position of intermodal transport to make it competitive with road transport. In particular, it would like to remove obstacles impeding the use of intermodal transport between Western Europe and the Central and Eastern European Countries (CEECs). This paper describes work performed for the EC that examined the existing intermodal transport system, identified the major bottlenecks in the system, and identified and prioritized policies that the EC might implement for reducing the negative effects of the bottlenecks. The paper is divided into two parts. The first part describes the identification and prioritization of bottlenecks. Through desk research and surveys of forwarders, terminal operators, and link operators, we identified 35 groups of bottlenecks. These were prioritized using a set of eleven performance criteria determined based on surveys. In the second part of the paper, we describe the identification and prioritization of policies. One or more policies were identified to help solve each of the bottlenecks. The resulting set of 70 policies was evaluated and prioritized by experts using six performance criteria and five feasibility criteria. A final set of seven policies for reducing the negative effects of the most important bottlenecks was recommended to the EC.

INTRODUCTION

This paper reports on some of the major results of a project entitled INTERMODA (Integrated solutions for intermodal transport between the EU and the CEECs). The INTERMODA project was funded by the European Community (EC) within its Fifth Framework Programme under the ‘Competitive and Sustainable Growth’ Programme. The project was designed to contribute to the creation of an integrated transport system across Europe – between the fifteen current members of the European Union (EU) and 16 Central and East-European Countries (CEECs) (Bulgaria, the Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Romania, Slovakia, Slovenia, Turkey, Albania, Bosnia and Herzegovina, Croatia, Macedonia, and Yugoslavia). It was also designed to contribute to the objectives of a Common Transport Policy (CTP) in Europe.

The improvement of intermodality between the EU and the CEECs is expected to make an important contribution to the development of a sustainable transport system in Europe. However, there are many obstacles impeding an increase in the use of intermodal transport. As part of the INTERMODA project, we examined the existing intermodal transport system linking the present EU countries and the CEECs, identified the major bottlenecks in the system, and identified and prioritized policies that the EC might implement for reducing the negative effects of the bottlenecks.

The paper is divided into two major sections. The first section describes the identification and prioritization of bottlenecks restricting the use of intermodal transport. One of the major objectives in this part of the project was to improve our understanding of the reasons transporters, forwarders, and others choose one transport route over another and choose unimodal transport over intermodal transport. The second section describes the identification and prioritization of policies for helping to solve the bottlenecks. This process led to the recommendation of seven promising policies for reducing the negative effects of the most important bottlenecks.

IDENTIFYING AND PRIORITISING BOTTLENECKS IN THE INTERMODAL TRANSPORT SYSTEM

Defining the Intermodal Transport System and Bottlenecks

The intermodal transport system consists of the entire flow of goods on the entire transport infrastructure network, over all modes and transport vehicles, together with all related services (such as transshipment, storage, etc.) and service providers. The intermodal transport network consists of nodes and links. A node is a terminal where goods are loaded onto a mode or transhipped from one mode to another. A link is a connection between two terminals along which the mode of transport cannot change. Bottlenecks can also occur at national borders, which can be considered virtual nodes.

An intermodal bottleneck is an actual or perceived negative characteristic of an intermodal door-to-door transport chain that makes intermodal transport less attractive than unimodal transport. Although some bottlenecks will equally affect all types of transport (unimodal, multi-modal, intermodal, combined transport), we were interested only in those that have an impact on the choice for intermodality. Bottlenecks can appear individually (an otherwise efficient system disrupted by a single problem) or through an accumulation of inefficiencies (e.g. narrow and ill-maintained roads, outdated equipment, inefficient handlers at terminals, resulting in long delays).

Bottlenecks can be located at pressure points on the intermodal transport network; that is, they can occur in individual elements, such as:

- at the origin;
- during transport (i.e., on the links);
- at points of transshipment (i.e., at terminals);
- at virtual nodes, such as borders;
- at the destination.

The entire route (or large parts of it) from origin to destination could be a bottleneck. Bottlenecks can also be systemic (e.g. legal inefficiencies that affect all intermodal transport in an entire region or country). This means that, in more general terms, bottlenecks can occur in:

- finding the intermodal solution (this is an information problem: do transporters know about their alternatives?);
- transporting goods between nodes;
- loading, unloading and transshipment;
- the general context of transport in a region or country.

Bottlenecks can be distinguished according to different criteria. In INTERMODA we used a categorization based on the level of detail of the analysis that distinguishes among three types of bottlenecks:

- **specific bottlenecks**, which occur at only one location and can be solved through national policy. (For example, Riga suffers from a lack of ring roads and a city layout that makes through transport difficult).
- **common bottlenecks**, which occur at multiple locations but are specific to their location. No general action can be undertaken to eliminate common bottlenecks at all locations. (For example, many terminals have poor road access.)
- **generic bottlenecks**, which are inherent to the system. They occur at multiple locations but are identical in nature at all locations. A generic bottleneck is of the same nature everywhere and could be solved by a general policy. (For example, the railways systems in different countries have different gauge widths.)

Our methodology for identifying bottlenecks in the intermodal transport system consisted of four steps:

- Step 1. Identify the major freight corridors between the CEECs and Western Europe and their associated freight flows
- Step 2. Identify the major transport routes within each corridor
- Step 3. Identify the major bottlenecks on each of the intermodal routes
- Step 4. Prioritize the intermodal bottlenecks

These steps are described in the following four subsections.

Step 1: Identify the Major Freight Corridors

A corridor is a geographically defined “channel” through which a significant volume and concentration of transport flows pass. In order to determine the major transport corridors between Western Europe and the CEECs, we investigated the sizes and directions of the major transport flows, represented in the form of flows in tonnes between origin regions (O) and destination regions (D), using an O/D matrix of flows for the year 2000 that was created as part of the project. This analysis resulted in the identification of four major freight corridors. The first flow (corridor A in Figure 1) is the Northern European flow, going from North-West Europe (seaports, such as Hamburg and Bremen) and Scandinavia to the Baltic States and then on to Belarus and Russia. The second flow (corridor B in Figure 1) is the flow from North Western Europe to Poland on to Belarus and Russia. The third flow (corridor C in Figure 1) represents flow from North Western Europe to South Eastern Europe. The fourth flow (corridor D in Figure 1) goes from Southern Europe to South Eastern Europe and from Southern Europe towards Scandinavia.

Step 2. Identify The Major Transport Routes Within Each Corridor

A route is a set of links and nodes within the transport system that is used to carry goods from a specific origin node to a specific destination node. Within each corridor we identified the most important routes. Our approach in this step consisted of three parts. First, we interviewed a number of freight forwarders in Western Europe and the CEECs and asked them to describe their major routes (each was asked to describe two routes: a unimodal route and an intermodal route). Second, the O/D matrix supplied additional routes. Third, we obtained routes by examining services offered by forwarders on the Internet. The final selection of routes was based on the amount of freight flow along the route and the geographic spread among the routes. This process resulted in 19 selected intermodal routes (three in Corridor A, three in Corridor B, nine in Corridor C, and four in Corridor D).

Step 3. Identify The Major Bottlenecks On Each Of The Intermodal Routes

In this step, each of the 19 selected intermodal routes was investigated in detail using information from the forwarder interviews, interviews with experts, and desk research. This resulted in the list of 15 common bottlenecks and 7 generic bottlenecks shown in Table 1.

Step 4. Prioritize The Intermodal Bottlenecks

In this step we ranked the bottlenecks according to the urgency of their removal, where urgency is defined by the impact of removal on the development of intermodal versus road transport. The method that we used to determine the ranking of the bottlenecks consists of three components:

1. develop criteria for the prioritization of bottlenecks,
2. combine the conclusions with the input of experts,
3. determine a ranking of common and generic bottlenecks.

We decided that the criteria for prioritization should cover the main determinants of modal choice and capture the areas that are most in need of improvement and that have the biggest potential for improvement. In particular, the most important bottlenecks:

- are related to the major determinants of the choice for intermodal rather than road transport
- relate to aspects for which intermodal transport has a disadvantage over road transport or that lower its performance with respect to aspects for which it has an advantage over road transport
- that when removed have the largest potential impact on the (relative) growth of intermodal transport

The interviews with forwarders contained a question on the advantages and disadvantages of intermodal transport relative to road transport (see Figure 2). The question involved a simple judgment, based on experience with and understanding of the industry. No ranking or quantitative assessment was required. As a result, the answers appear to be consistent in that both interviewers and interviewees seem to have interpreted the question in the same way and have provided answers of the same quality.

The forwarders were asked to assess the advantage or disadvantage of intermodal transport with respect to eleven aspects. Table 2 describes these aspects.

By rating the aspects, the forwarders provided us with information that allowed us to assess the importance of each aspect to the performance of intermodal transport relative to road transport. The 25 sets of answers from the interviews with the forwarders were analyzed to create frequency tables and to calculate descriptive statistics. Figure 3 summarizes the results of this analysis. The information in the figure suggests that the primary strengths of intermodal transport are costs, scale or volume, safety and security, while its weaknesses are travel time and flexibility. In addition, the results suggest that intermodal transport has an advantage in tracking and tracing of freight and a disadvantage in its legal requirements.

The crucial question is how to link the ranking of advantages and disadvantages to the list of common and generic bottlenecks. Linking these will enable us to prioritize bottlenecks. Each bottleneck affects one or more of the aspects that determine the choice for or against intermodal transport. Three types of effects can be distinguished:

- Direct effects — The bottleneck translates directly into lower performance with respect to one of the determinants of mode choice. For example, poor equipment leads to longer handling times, which translates directly into longer travel times.
- Indirect derived effects — The bottleneck has a direct effect on one aspect and, by changing the performance relative to that particular aspect, it also affects other aspects. For example, longer handling times directly translate into longer travel times, and by extending the travel time they indirectly raise the level of costs.
- Indirect implied effects — the bottleneck does not directly affect an aspect but it most likely will influence the performance of intermodal transport with respect to that aspect. For example, poor transshipment equipment increases the possibility of damage to containers and goods (safety) and may reduce the volume of individual consignments that can be transshipped.

Assuming that, within a group, improving the aspect in which intermodal transport has an advantage (e.g. cost) is to be preferred to improving an aspect in which intermodal transport has a disadvantage (e.g. travel time), and only considering direct effects, produces the ranking of bottlenecks (from higher to lower importance) shown in Table 3.

We convened a workshop with experts on intermodal transport to discuss the common and generic bottlenecks we had identified, to add ones that they thought were missing, and to assign priorities. This exercise plus subsequent analysis led to a final list of 23 common bottlenecks and 12 generic bottlenecks (in total, 35 bottlenecks), which were divided into four groups:

- Terminals
- Capacity of links
- Interoperability
- Market conditions

Each group contains bottlenecks of a comparable or homogeneous type that can be addressed using similar policies. In fact, it is possible that a single policy will have effects on some or all of the bottlenecks in a group. At the workshop, each of the 35 bottlenecks was assigned an importance classification (high, medium, and low) by the experts, by RAND Europe, and by the other members of the consortium. These ratings were then combined, to produce an overall rating (high, medium, or low) for each of the bottlenecks.

This process resulted in the categorization and prioritization shown in Table 4. It must be noted that within their level of rating (high, medium, low) the bottlenecks are not ranked; they are bundled into the four above-mentioned groups.

IDENTIFYING AND PRIORITISING POLICIES FOR REDUCING BOTTLENECKS IN THE INTERMODAL TRANSPORT SYSTEM

Description of the Method Used

Figure 4 provides an overview of the steps in the policy assessment. The four steps shown in the figure are aggregations over the six steps (A-F) that are explained in detail below. The aggregate steps (and their correspondence with the detailed steps) are:

1. Identify and prioritize the bottlenecks (Step A)
2. Identify policy measures for the bottlenecks (Step B)
3. Evaluate policy measures on performance and feasibility (Step C-E)
4. Rank the policy measures and identify the most promising (Step F)

Identify and Prioritize the Bottlenecks

(Step A) The previous section described how we identified and prioritized 23 common bottlenecks and 12 generic bottlenecks. These 35 bottlenecks, which are listed in Table 4, form the basis for the policy assessment described in this section.

Identify Policy Measures for the Bottlenecks

(Step B) For each bottleneck, we identified one or more policy measures that might help solve it. These policies came from the existing literature and from brainstorming within the project team. This process resulted in a list of 70 policy measures (there are one or more measures for each bottleneck, and some measures apply to several bottlenecks).

Evaluate Policy Measures on Performance and Feasibility

(Step C) The policy measures were assessed in two steps:

1. The partners evaluated each of the 70 policies on each of six aspects of performance and five aspects of feasibility.
2. Nine experts examined the partners' evaluations and suggested changes.

The six aspects of performance assessment are:

1. Travel time: What would be the effect on travel time?
2. Costs: What would be the effect on the transport costs?
3. Flexibility: What would be the effect on flexibility?
4. Reliability: What would be the effect on reliability (length and frequency of delays)

5. Safety: What would be the effects on safety?
6. Security: What would be the effects on security? Are goods better or less well protected?

These aspects are a subset of the aspects that were used to assess the bottlenecks. The six selected aspects are aspects that are end objectives. Other aspects from the bottleneck assessment were not used because they are means objectives, rather than end objectives. For example, legislation is a means for achieving successful intermodal transport, but creating or changing legislation is not an end in itself.

The partners were asked to indicate if they thought a policy measure would have a strong positive (+2), a positive (+1), a negative (-1) a strong negative (-2) or a neutral (0) effect on the bottleneck. They could also add one or two additional bottlenecks that the policy might affect.

The five aspects of feasibility assessment related to the implementation of a policy measure are:

1. Financial consequences: The degree to which the implementation of the policy can be financed and managed. This indicator is related to the amount of resources estimated to be required for construction and operation
2. Technological possibilities: Whether it is possible by 2020 to adopt the necessary new technologies or whether the new technologies are compatible with the existing infrastructure
3. Political climate: The level of political support for the measure (e.g., does the measure go against current policy?)
4. Public acceptance: The degree to which the public (including firms, pressure groups and other institutional organizations) are likely to accept the policy
5. Institutional complexity: Does the policy fit into current legal and institutional structures or are major problems foreseen that may hinder implementation?

The partners could indicate per aspect if the implementation of the policy measure would be very easily feasible (+2), slightly feasible (+1), feasible, not easily, but also not with great difficulty (0), slightly infeasible (-1) or infeasible (-2).

For each policy and each of the 11 aspects, the results from the first step (among partners) were averaged and the standard deviation was calculated. The standard deviation was used to identify disagreements, which were then addressed and resolved.

(Step D) Nine experts were then asked to judge the assessed policies from Step C. If they disagreed with the scores, they could revise them. Space was provided for them to explain their revisions. As in the first step, the score for a policy measure on each of the six performance aspects and on each of the five feasibility aspects could range from a strong positive (2) through neutral (0) to a strong negative. To get more detail into the scoring, they were allowed to use increments of 0.5 (this was a change from the scoring used in the first step).

(Step E) The results from the policy assessment (Step D) were then analyzed. The final score for each policy was produced by taking weighted averages. The bottlenecks, performance aspects, and feasibility aspects were all assigned weights. In the bottleneck analysis described in the previous section, each bottleneck had been assigned to one of three categories: high priority, medium priority, or low priority. In the policy analysis, high-priority bottlenecks were assigned a weight of 3, medium-priority bottlenecks were assigned a weight of 2, and low-priority bottlenecks were assigned a weight of 1. In weighing the performance aspects, the aspects travel time and costs were recognized as most important and received a weight of 2, while all other aspects received a weight of 1. For feasibility, all aspects received a weight of 1. In order to give higher priority to policies affecting multiple bottlenecks, final performance scores were produced for each policy by dividing the policy's total performance score by the number of bottlenecks to which the policy related.

Summarizing the above procedure, the scores for a policy are obtained in three stages. Using the following symbols, the procedure is:

X_{kj} = the average (weighted) score for policy k on bottleneck j over all six of the performance aspects

Y_k = the average (weighted) score for policy k over all five of the feasibility aspects

Z_k = the final score for policy k

P_{ikj} = policy k's score on performance aspect i (i = 1, 2, . . . , 6) for bottleneck j

p_i = the weight assigned to performance aspect i (i = 1, 2, . . . , 6)

F_{mk} = policy k's score on feasibility aspect m (m = 1, 2, . . . , 5)

f_m = the weight assigned to feasibility aspect m ($m = 1, 2, \dots, 5$)

b_j = the weight assigned to bottleneck j

n_k = the number of bottlenecks associated with policy k

Stage 1: Calculate the performance score of policy k for bottleneck j

$$X_{kj} = \sum_{i=1}^6 p_i \cdot P_{ikj}$$

Stage 2: Calculate the feasibility score for policy k

$$Y_k = \frac{\sum_{m=1}^5 f_m F_{mk}}{\sum_{m=1}^5 f_m}$$

Stage 3: Calculate the final performance score for policy k

$$Z_k = \frac{\sum_{j=1}^{n_k} b_j \cdot X_{kj}}{n_k}$$

Evaluate Policy Measures on Performance and Feasibility

(Step F) The policy measures were ranked in descending order based on the final performance scores calculated in Step E. The ranked list of policy measures was divided into three groups: high impact policies (scores above 2), medium impact policies (scores between 1 and 2), and low impact policies (scores below 1). The feasibility scores were used to assign the policies to three feasibility categories: good (scores above 0.5), neutral (scores between 0 and 0.5), and poor (scores below 0).

Prioritizing the Policies

The first step in our analysis of the results was to perform a simple ranking of policies according to their performance scores. Tables 5, 6, and 7 present this ranking according to the three performance categories (high, medium, and low) and associate each policy with its feasibility category (poor, neutral, or good).

In order to focus our attention toward the most important policies, we combined the ranking of policies with the ranking of bottlenecks. This allowed us to identify policies that have a high impact on highly important bottlenecks. Such policies are more likely to improve not only individual bottlenecks, but also the development of the European intermodal transport system as a whole. Table 8 shows the relationships between bottlenecks and policies. The aim of the policies recommended by INTERMODA was to achieve the largest possible effect on intermodal transport by efficiently concentrating scarce resources. We therefore focused the policies primarily on addressing the problems of high and medium importance bottlenecks. The most effective methods of eliminating such bottlenecks are provided by the high and medium performance policies. We have consequently not included the low-importance bottlenecks and the low-impact policies in Table 8.

Of the initial 70 policies, 19 are high-impact policies, 30 are medium-impact policies and 21 are low-impact policies; 12 policies have poor feasibility, 48 have neutral feasibility and 12 have good feasibility. Of the 19 high-impact policies, 2 have poor feasibility, 10 have neutral feasibility and 7 have good feasibility. The 7 high-impact policies with good feasibility affect half of the high-importance bottlenecks.

The 19 high-impact policies are primarily targeted at changing and standardizing legislation or at creating financial possibilities for the development of intermodal transport. The creation of financial possibilities for the building of new infrastructure is considered to be much less feasible than the upgrading of existing infrastructure (which has either a neutral or a good feasibility). The high-impact policies are also generally targeted at improving operations by better utilizing or upgrading infrastructure and equipment.

Policies that target bottlenecks that do not concern either infrastructure or equipment —e.g. policies to train personnel or to improve the environment— are expected to have low impact. The experts also concluded that a marketing campaign aimed at encouraging the use of intermodal transport and support for the increased use of ICT are expected to have little impact.

The gray-colored box in Table 6 shows the combination of high-impact policies and high-importance bottlenecks. Of the 19 high-impact policies 7 have good feasibility. These are targeted at 8 out of the 16 high-importance bottlenecks. These 7 policies fall into three categories, and can be summarized as:

1. **Modernization.** Introduce mechanisms to facilitate:
 - the replacement of obsolete handling equipment
 - the improvement of terminals
 - the improvement of terminal operations
 - the restructuring of railroad networks
2. **Standardization.**
 - Set standards for combined transport equipment
 - Standardize and reduce safety checks at borders
3. **Safety.**
 - Check safety at departure and arrival (and not at borders)

These 7 policies are the best candidates for forming policy packages and are the ones that we recommended as the highest priority to the European Commission.

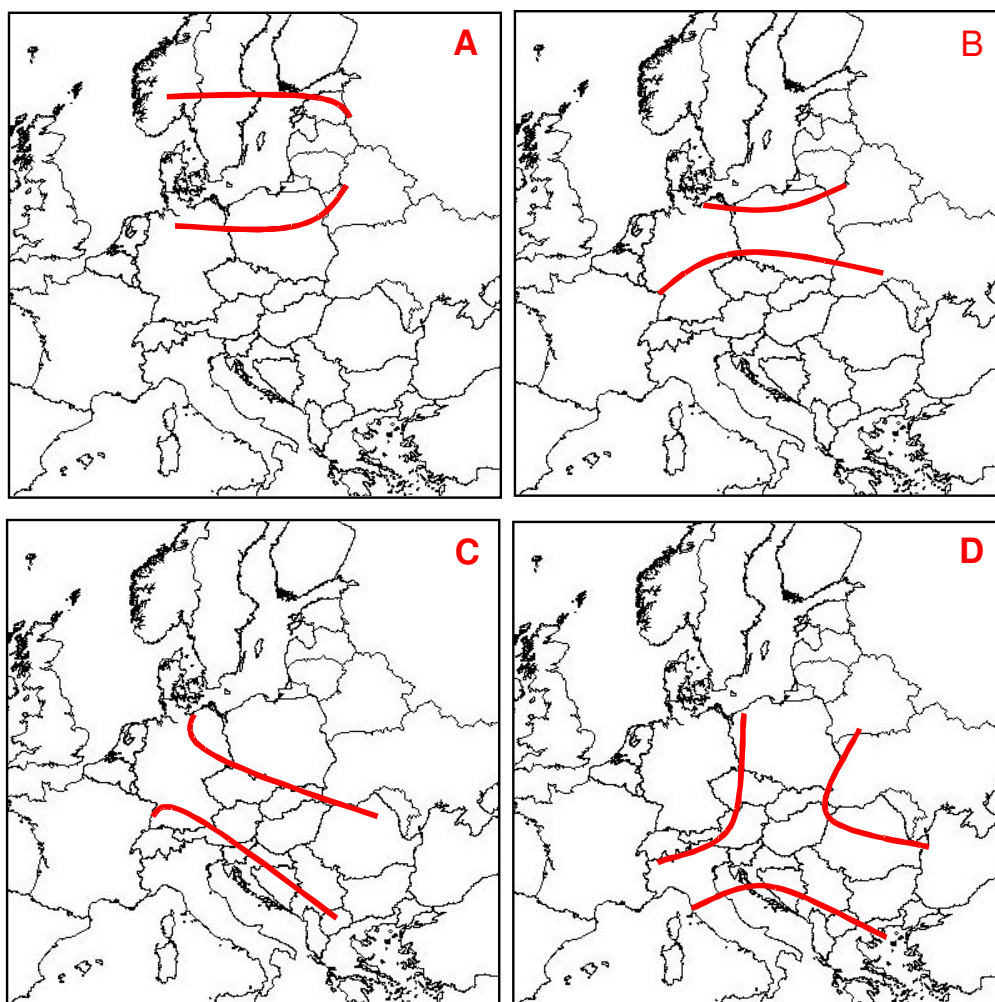

ACKNOWLEDGMENT

The INTERMODA project was carried out by a consortium in which RAND Europe was one of eleven partners. Further details about the project, including copies of the executive summaries of reports and results can be found on the project's Website: www.intermoda.org.

Question on the Forwarder Questionnaire:
“Please compare intermodality to road transport on several factors. For each factor, use the following symbols to rate intermodal transport’s advantages and disadvantages.”

Compared to road transport, intermodal transport has a:

++	= strong advantage
+	= slight advantage
O	= neutral
-	= slight disadvantage
■	= strong disadvantage

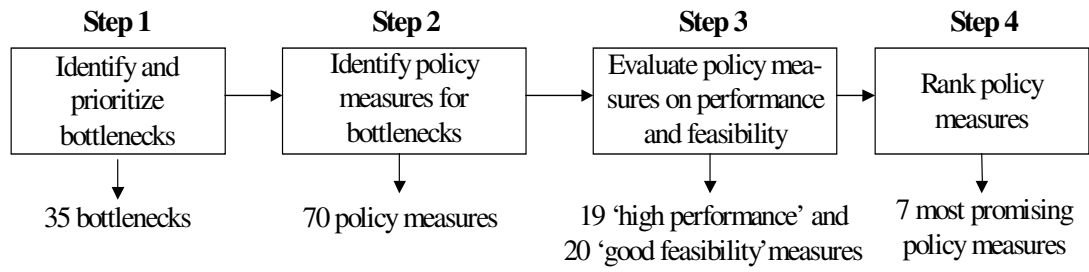

FIGURE 4 Method for Identifying Promising Policy Measures

TABLE 1 Common and Generic Bottlenecks

Number	Description of Bottleneck
COMMON BOTTLENECKS	
C1	Poor railway connection between main line and terminal/port
C2	Large distance between terminal and main infrastructure network
C3	Large distance between terminal and marshalling yard
C4	Non-electrified tracks at terminals
C5	Poor road access to terminals
C6	Longer handling time due to poor equipment
C7	Long marshalling time due to short tracks and limited number of tracks
C8	Shortage of (intermodal) terminals
C9	Insufficient terminal capacity
C10	Inefficient rail network layout
C11	Insufficient rail capacity
C12	Narrow sections on waterways
C13	Limited capacity of locks at hydropower stations en-route.
C14	Low bridges on waterways
C15	Too complex and cumbersome data exchange
GENERIC BOTTLENECKS	
G1	Fixed opening times for terminals
G2	Different and inconsistent border crossing procedures
G3	Remote location of customs offices
G4	Different gauge width of railway system in different countries
G5	Different voltages in different countries
G6	Unequal market conditions for road and intermodal transport
G7	Interoperability

TABLE 2 Aspects of Intermodal Transport

	Aspect	Description
1	Costs	Is intermodal transport cheaper or more expensive?
2	Travel time	Does it take longer or is it quicker than road transport?
3	Reliability	Is intermodal transport more or less reliable? This question relates to the length and frequency of delays. The safety and security of transport are dealt with separately.
4	Flexibility	Can intermodal transport quickly adjust to changes in demand and in customer requirements, and is it available whenever needed?
5	Tracing of freight	Can the location and status of load units and cargo be checked easily?
6	Use of infrastructure	Is the quality and capacity of infrastructure (including terminals) sufficient for intermodal transport?
7	Scale/volume	Is intermodal transport better or less able to handle large volumes of goods than road transport?
8	Service of terminals	Do the services provided at terminals give intermodal transport (which uses these terminals) an advantage over road transport or do they make it more cumbersome?
9	Legislation	Does intermodal transport have legal advantages or are there legal bottlenecks that road transport can circumvent?
10	Safety	Do load units and cargo incur more or less damage in intermodal transport than in road transport?
11	Security	Are goods better or less well protected in intermodal transport?

TABLE 3 A Tentative Ranking of Common (C) and Generic (G) Bottlenecks

Ranking	Number	Description of Bottleneck
highest	G6	Unequal market conditions for road and intermodal transport
	G1	Limited opening times of terminals
	C11	Insufficient rail capacity
	G7	Interoperability in general
	C10	Inefficient rail network layout
	C13	Limited capacity of locks at hydropower stations en-route
	C7	Long marshalling time due to short tracks and limited number of tracks
	C9	Insufficient terminal capacity
	C2	Large distance between terminal and main infrastructure network
	C3	Large distance between terminal and marshalling yard
	C1	Poor railway connection between main line and terminal/port
	C5	Poor road access to terminals
	C12	Narrow sections on waterways
	C6	Longer handling time due to poor equipment
	C14	Low bridges on waterways
	C8	Shortage of (intermodal) terminals
	C15	Too complex and cumbersome data exchange
	C4	No electrified tracks at terminals
	G4	Different gauge width of railway system in different countries
	G5	Different voltages in different countries
G3	Remote location of customs offices	
lowest	G2	Different and inconsistent border crossing procedures

TABLE 4 Final Categorization and Prioritization of Bottlenecks

Priority	Group	Bottleneck
HIGH	Terminal – access	G1 Limited opening times of terminals
	Terminal – capacity	C8 Shortage of (intermodal) terminals
		C9 Insufficient terminal capacity
		C23 Lack of appropriate combined-transport (internal) equipment
	Terminal – operations	C7 Long marshalling time due to short tracks and a limited number of tracks
	Capacity of links – general	C17 Inadequate width and height of tunnels
	Capacity of links – rail	C11 Insufficient railroad capacity
	Capacity of links – inland waterways	C18 Shallow sections on waterways
	Interoperability – border crossing	G2 Different and inconsistent border crossing procedures
		G10 Countries have different weight limits
		G12 Lack of interoperability across national networks
	Interoperability – technical interoperability	G7 Interoperability in general
Market conditions – inadequate market information	G8 Lack of sufficient demand for intermodal services	
Market conditions – unfavorable cost structure	G6 Unequal market conditions for road and intermodal transport	
	G9 Lack of return freight, and cabotage	
Market conditions – legislation	C16 An inadequate legislative framework	
MEDIUM	Terminal – access	C5 Poor road access to terminals
	Terminal – operations	C6 Longer handling time due to poor equipment
	Capacity of links – rail	C10 Inefficient layout of the railroad network
	Interoperability – border crossing	G4 Different gauge width of railway systems in different countries
		G5 Different voltages in different countries
	Interoperability – technical interoperability	G11 Operational differences (signaling)
	Market conditions – inadequate market information	C20 Tariff setting takes too long
Market conditions – legislation	C22 Not all terminals can handle dangerous goods	
LOW	Terminal – access	C2 Large distance between the terminal and the main infrastructure network
	Terminal – operations	C4 No electrified tracks at terminals
		G3 Remote location of customs offices
	Capacity of links – general	C21 Lack of qualified personnel (especially locomotive drivers)
	Capacity of links – inland waterways	C12 Narrow sections on waterways
		C13 Limited capacity of locks at hydropower stations en-route
		C14 Low bridges on waterways
		C19 Spatial planning does not include the industrial parts of the inland waterways
Interoperability – border crossing	C21 Lack of qualified personnel (differences in qualifications and requirements)	
Market conditions – inadequate market information	C15 Too complex and cumbersome data exchange

	8 Introduce fund for expanding existing terminals		X	
	54 Enforce Technical Standards Across Modes		X	
	43 Set standards for the documentation of freight			X
	69 Set rules to harmonize working times	X		
	67 Increase the legal speed limits for trains		X	
	52 Set up program to improve market information		X	
	64 Introduce fund for improving transshipment facilities at stations where different gauges meet		X	
	57 Enable private funding (public-private partnership) for intermodal terminals			X
	63 Set standards for signaling equipment		X	
	34 Introduce Fund for using flexible wheel-based carriages		X	
	1 Introduce fund for relocation of terminals		X	
	49 Set rules to harmonize the enforcement of labor regulations		X	
	47 Introduce fund for introducing and performing logistics scans			X
	41 Set standards for signaling operations		X	
	36 Set standards for weight limits		X	
	53 Set standards for assessing liability in different modes		X	
	62 Introduce fund for the usage of more flexible transporter wagons		X	
	5 Include terminals in TEN			X
	35 Introduce fund for replacing common locomotives by multi-voltage locomotives		X	
	65 Stimulate the use of ICT		X	
	4 Introduce fund for constructing of infrastructure between terminals and the main network		X	
	60 Introduce fund for the usage of special low floor transport wagons		X	
	68 Set English as official language for train operations	X		
	17 Include railroad network in TEN			X
	3 Introduce fund for improving infrastructure between terminals and the main network			X
	58 Introduce fund for building extra storage facilities at terminals		X	

TABLE 7 Low-Performance Policies

Performance	Policy	Feasibility		
		Poor	Neutral	Good
LOW	48 Set rules to harmonize infrastructure charges	X		
	27 Subsidize the use of shallow-drawing ships		X	
	37 Set standards for the carrying-capacity of new roads		X	
	2 Introduce fund for concentration of terminals		X	
	22 Introduce Double-Stack Trains		X	
	13 Relocate Customs Offices to Terminals			X
	38 Set up a European training institute for rail personnel			X
	28 Stimulate the inclusion of development of inland waterway ports as logistic centers in existing and new zonal plans			X
	24 Introduce fund for increasing lock capacities		X	
	56 Introduce fund for investing in special storage facilities and handling equipment for dangerous goods	X		
	59 Change customs regulations to enable custom procedures to be carried out directly at the premises of the client			X
	44 Introduce fund for investments in ICT applications for tracking and tracing		X	
	25 Introduce fund for raising low bridges on waterways	X		
	45 Start marketing campaign for intermodal transport			X
	70 Set European qualification standards for personnel		X	
	46 Introduce fund for investing in ICT applications for tariff setting			X
	66 Set higher standards on the number of wagons per train		X	
	55 Adjust legislation to allow dangerous goods to stay in terminals without storage facilities for more than 24 hours	X		
	50 Set standards for environmental impacts	X		
	51 Set environmental charges	X		
16 Determine alternative routes to avoid low-capacity tunnels and encourage their use			X
